

Lab 9

Create the following code in the Vehicle Information System to satisfy the following requirements.

A Vehicle management system has to keep track of vehicles. Create a **VehicleManagement** class with the following functionality.

1. Every vehicle that is Registered has to be added to a HashMap object **vehs** in the **VehicleManagement** class.
2. The Key is the registrationNo, Value is a **vehReg** object with two string arguments- chasisNo and ownerName.
3. Give methods to retrieve Vehicle objects using a) registrationNo b) insuranceNo c) ownerName as a set of vehicles owned by a given owner.

Lab 7

1. The Vehicle class has an Inner class called **VehicleInsurance**
2. **VehicleInsurance** is a concrete class with fields **int insuranceNo**, **String insuredUpto**, **String insurersName**. Constructor having arguments to take one **int** and two **String** arguments.
3. All Vehicles will have an Object of **VehicleInsurance** class called **vehIns** which will be created in their Constructors.

Bootcamp_1.1

1. The Vehicle class has a Nested class called **VehicleRegistration**
2. **VehicleRegistration** is a concrete class with fields **int registrationNo**, **String chasisNo**, **String ownerName**. Constructor having arguments to take one **int** and two **String** arguments.
3. All subclasses of Vehicle will have an Object of **VehicleRegistration** class called **vehReg** which will be created in their Constructors.
4. Sort the **vehObjArray** using **ownerName**.

Bootcamp 1

1. Vehicle Class should be Abstract.
2. Vehicle class implements the interface **Comparable** but leave the method **compareTo** as abstract
3. All other classes will be concrete and will be giving implementation for **compareTo** using **horsePower** to compare the Vehicles.
4. Create a Main class which creates an Array of objects of Vehicle type **vehObjArray**. For each type of vehicle create and add two objects. Bike, Car and Truck.

5. Sort the **vehObjArry** using horsepower.
